DS5020
Mini Project 1 Reflection
Alex Katzman

Most of the coding I did for the project was for data engineering logic. There were a couple of transformations I had to make to get the data into a usable format, but it was mostly straightforward. One of the first steps I took was exploring the data to figure out what the product code actually represented, and then splitting it up into three features: product code, variation, and a non product flag. The non product flags represent transactions other than a purchase, so they are all dropped. I collapsed the variations into one product to reduce noise.

There was a bit of misunderstanding when I passed off the data to my teammate. I did not realize the country and product name features would still be needed for the analysis, but fortunately we were able to work out the issue. I should have made a point to read through the instructions more carefully since they were extremely detailed.

Overall, I think the project went well. I reviewed Adrien's code and wrote up the memo to make sure I understood the concepts. The data engineering did not directly require looking at PCA or SVD, so it made sense for me to write the overview, even though he actually made most of the decisions discussed in it.
